Wrangling data with dplyr

2019-08-15

dplyr: go wrangling

The main verbs of dplyr

select()

filter()

mutate()

arrange()

summarize()

group_by()

The main verbs of dplyr

```
select() = Subset columns (variables)
```

filter()

mutate()

arrange()

summarize()

group_by()

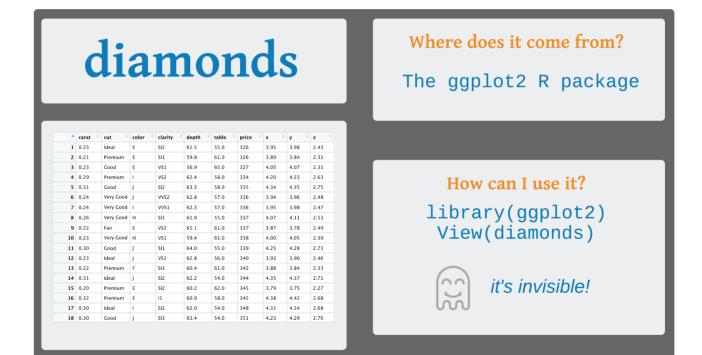

select(<DATA>, <VARIABLES>)

```
select(<DATA>, <VARIABLES>)
diamonds

```

Detour: The Pipe

%>%

Passes the result on one function to another function

Detour: The Pipe

```
diamonds <- arrange(diamonds, price)
diamonds <- filter(diamonds, price > 300)
diamonds <- mutate(diamonds, log_price = log(price))
diamonds</pre>
```

Detour: The Pipe

```
diamonds <- diamonds %>%
  arrange(price) %>%
  filter(price > 300) %>%
  mutate(log_price = log(price))

diamonds
```

Keyboard shortcuts

Insert <- with alt/opt + -</pre>

Insert %>% with ctrl/cmd + shift + m

Use %>% to write a sequence of functions that:

- 1. Filter only countries that are in the continent of Oceania.
- 2. Select the country, year and lifeExp columns
- 3. Arrange the results so that the highest life expetency is at the top.

```
gapminder %>%
  filter(continent == "Oceania") %>%
  select(country, year, lifeExp) %>%
  arrange(desc(lifeExp))
## # A tibble: 24 x 3

Challenge!

- 1. Import the diabetes data from the importing data. A copy of the CSV file is available in this folder.
- 2. Add the variable bmi to the data set using height and weight using the formula: (weight / height^2) * 703
- 3. Select just id, glyhb, and the new variable you created.
- 4. Filter rows that have BMI > 35. How many rows and columns are in your new data set?

```
diabetes <- read_csv("diabetes.csv")
diabetes %>%
  mutate(bmi = (weight / height^2) * 703) %>%
  select(id, glyhb, bmi) %>%
  filter(bmi > 35)
```

```
diabetes <- read_csv("diabetes.csv")
diabetes %>%
  mutate(bmi = (weight / height^2) * 703) %>%
  select(id, glyhb, bmi) %>%
  filter(bmi > 35)
```

```

The main verbs of dplyr

```
select()
```

filter()

mutate()

arrange()

summarize() = Summarize the data

group_by() = Group the data

summarize()

summarize(<DATA>, <NAME> = <FUNCTION>)

summarize()

```
summarize(diamonds, n = n(), mean_price = mean(price))

### # A tibble: 1 x 2
### n mean_price
### <int> <dbl>
### 1 53940 3933.
```

Use summarise() to compute three statistics about the gapminder data set:

- 1. The first (min()) year in the data
- 2. The last (max()) year in the data
- 3. The total number of observations (n()) and the total number of unique countries in the data (n_distinct())

1 1952 2007 1704

142

group_by(<DATA>, <VARIABLE>)

```
diamonds %>%
  group_by(cut)
```

```
diamonds %>%
  group by(cut)
## # A tibble: 53,940 x 10
## # Groups: cut [5]
4F4F
     carat cut color clarity depth table price
                                               Χ

```
mutate_if/all/at()
summarize_if/all/at()
... etc!
```

Joining data

Use left_join(), right_join(), full_join(), or inner_join() to join datasets

Use semi_join() or anti_join() to filter datasets against each other
